AWS X-Ray

(with Fargate and Lambda)

Doug Toppin AWS DC Meetup 15-Oct-2019

Agenda

- What is it
- Why use it
- What does it cost
- How does it work
- Where did it help me
- How did I use it
- Demo
- Lessons learned
- Links

What is it

"AWS X-Ray helps developers analyze and debug production, distributed applications, such as those built using a microservices architecture. With X-Ray, you can understand how your application and its underlying services are performing to identify and troubleshoot the root cause of performance issues and errors. X-Ray provides an end-to-end view of requests as they travel through your application, and shows a map of your application's underlying components. You can use X-Ray to analyze both applications in development and in production, from simple three-tier applications to complex microservices applications consisting of thousands of services."

Why use it

- Collect and display application performance metrics
- Gives insight into how an application is performing and at granular levels
- Metrics comparison after deployments provides immediate indication of performance differences or where issues might be occurring
- Very cost effective
- If it saves any labor/time in awareness or while troubleshooting it is worth the cost
- Cost can be dialed up/down by changing sampling level

What does it cost

- The first 100,000 traces recorded each month are free.
- The first 1,000,000 traces retrieved or scanned each month are free.
- If you have an application which receives 2,000 incoming requests per hour and you're using a 10% sampling rate, then your cost would be calculated as follows:

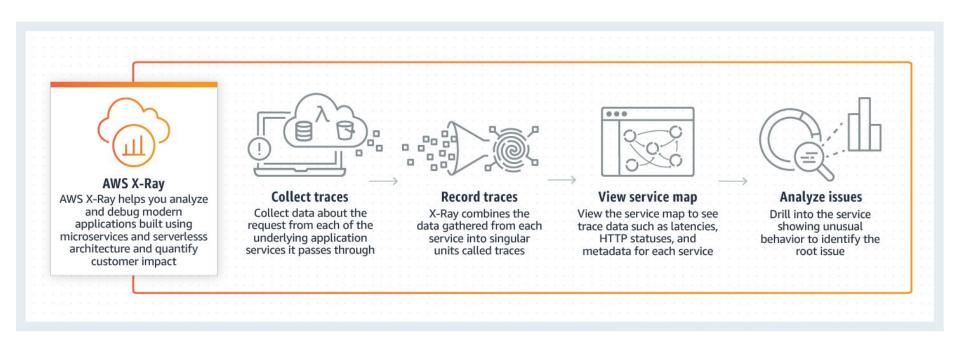

Traces Recorded

- Traces Recorded per Month = 2,000 requests per hour x 24 hours x 31 days x 10% = 148,800 traces
- Billable Traces Recorded per Month = 148,800 traces 100,000 traces in free tier = 48,800 traces
- Monthly Traces Recorded Charges = 48,800 traces * \$0.000005 = \$0.24

How does it work

- Container, my Python Flask use example
 - Instrumentation data sent to an agent installed in the container, it could have been an independent container in the Fargate task
 - Agent forwards to service
- Lambda, my email processing function
- EC-2
 - Agent installed on instance and forwards to service
- Non-AWS resource, such as your machine
 - Agent installed and running
- Application can send directly to service without using an agent

How does it work

Where did it help me

- Within the first 2 days of use it revealed where performance bottlenecks in aws s3 calls were occurring
- On 3 other occasions it provided an immediate indication of where performance issues were occurring or improvements had appeared after a deployment

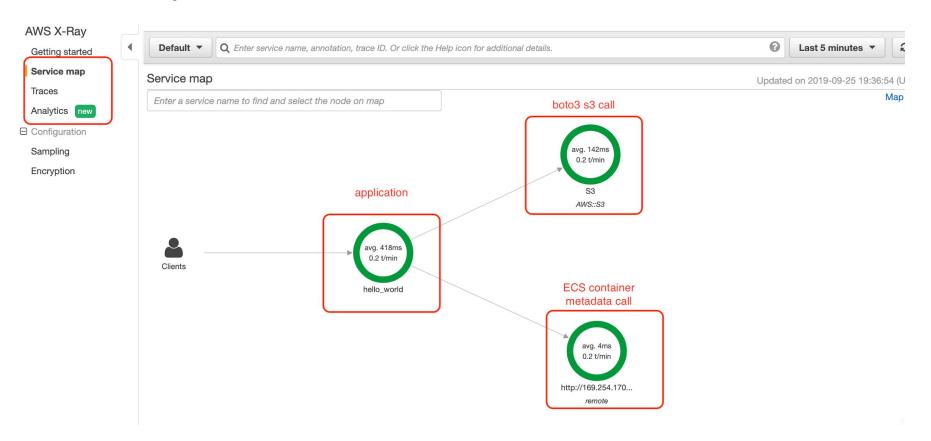

How did I use it

- Python Flask apps running in Fargate
 - o S3
 - o DynamoDB
 - SNS/SQS
- Lambda functions
 - o S3
 - o SES

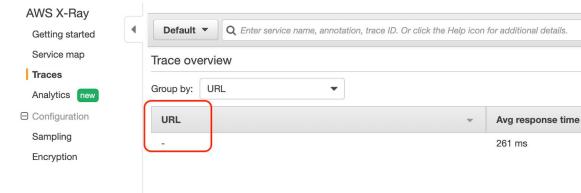

Demo

- Python Flask application running in Fargate
 - Created and deployed using the AWS Fargate cli
- Lambda function
 - Created and deployed using AWS cli

Demo system map

Demo traces

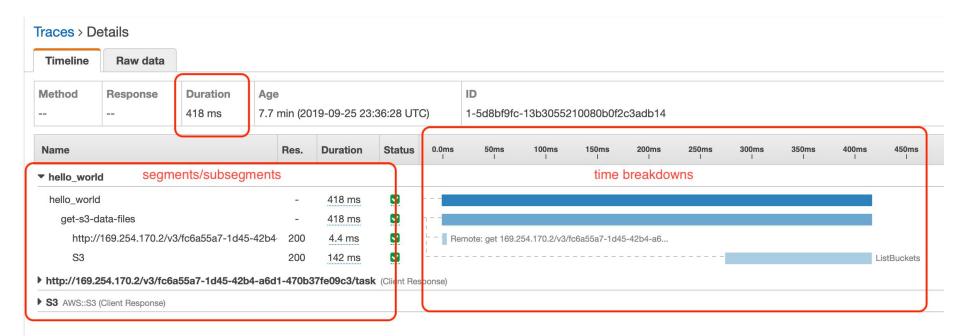

% of Traces

Last 15 minutes ▼

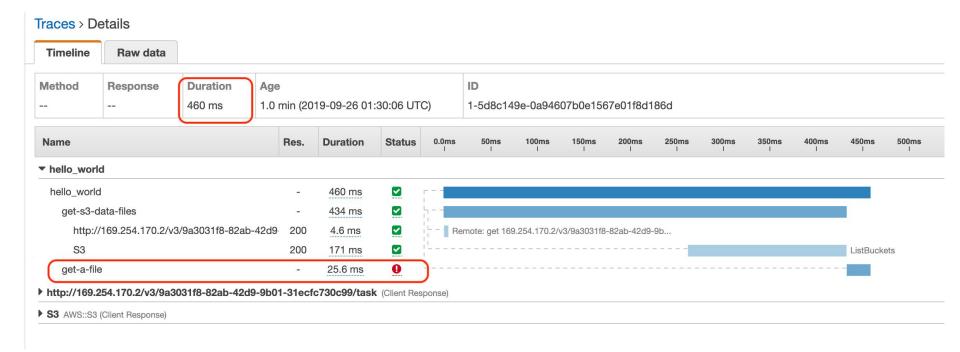

Done 100% scanned (found 2

Response

Demo trace

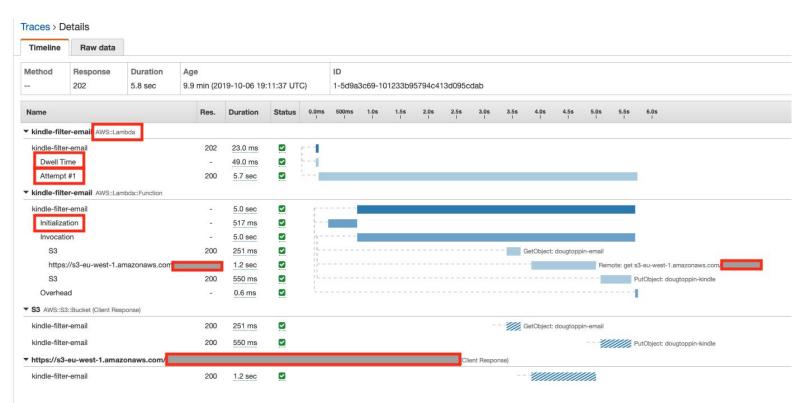

Demo comparisons after a deployment

Demo Lambda

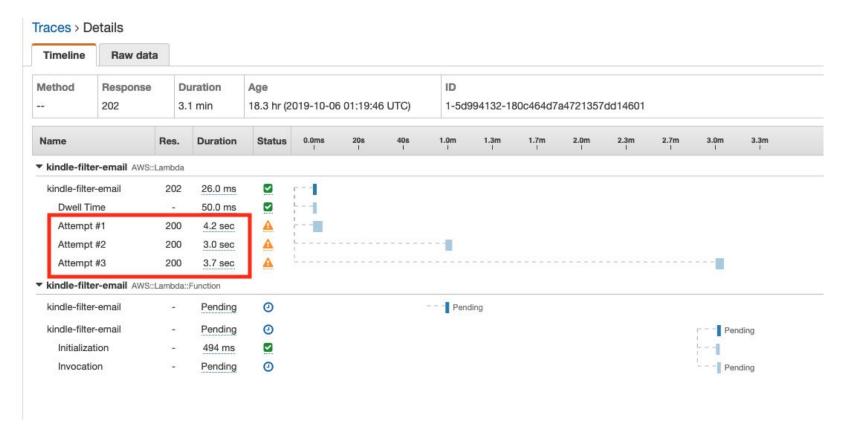

Demo Lambda metrics

Demo Lambda metrics definitions

- Dwell time time spent in Lambda service queue
- Invocation attempts retries
 - https://docs.aws.amazon.com/lambda/latest/dg/retries-on-errors.html
 - "Asynchronous Invocation Lambda retries function errors twice. If the function doesn't have enough capacity to handle all incoming requests, events may wait in the queue for hours or days to be sent to the function. You can configure a dead-letter queue on the function to capture events that were not successfully processed. For more information, see Asynchronous Invocation."
- Initialization function initialization code run before the handler

Demo Lambda attempts - default timeout too short

Demo comparisons over time

Demo deployment with fargate cli

```
Makefile
run:
     fargate task run app --subnet-id ${SUBNET} --security-group-id ${SG} --task-role ${ROLE}
stop:
     fargate task stop app
info:
     $(eval IP:= $(shell fargate task info app --no-color --no-emoji|grep IP|sed -n 's/^.*: //p'))
     @curl http://${IP}:8080
```

Lessons learned

- Instrument all external service calls
- Instrument all application compute bound functions
- Name segments and subsegments in a fashion that makes sense later
- Name segments in a manner that makes them easy to distinguish or filter on when you have multiple parallel environments, example is cluster name prefixes
- Make sampling level easily configurable to keep cost down
- Plan to include additional metadata in traces to allow more filtering later
- Decide what you want to be a segment, container start or request processing start?
- Filter out health check path using local sampling configuration
